Katie Boa Biologist

# **INTRODUCTION**

Ecological Land Services, Inc. (ELS) is part of the consulting team with Fischer Bouma Partnership (FBP) and Map Limited, Inc. (Map) that was contracted by Kitsap County Department of Public Works (KCPW) to conduct a feasibility report for the Port Gamble Trail between the Town of Port Gamble and Stottlemeyer Road NE in North Kitsap County. The trail is proposed by KCPW and Olympic Property Group (OPG) and crosses both County and OPG property. The project covers approximately 6 miles in Sections 7, 13, 18, 19, 24, 25, 30, 31, and 36, Township 27 North, Ranges 1 and 2 East of the Willamette Meridian, in the Port Gamble area of Kitsap County, Washington (Figure 1). This feasibility report summarizes findings of the wetland delineation conducted along the path in accordance with the *Kitsap County Code (KCC), Chapter 19.200 Wetlands* and for delineation methodology, wetland categorization, and mitigation requirements. It also provides estimates for wetland and buffer mitigation areas and costs.

## **METHODOLOGY**

The wetland delineation followed the Routine Determination Method according to the U.S. Army Corps of Engineers, Wetland Delineation Manual (Environmental Laboratory 1987) and the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys and Coast Region, Version 2.0 (U.S. Army Engineer Research and Development Center, 2010).

The Routine Determination Method examines three parameters—vegetation, soils, and hydrology—to determine if wetlands exist in a given area. Hydrology is critical in determining what is wetland, but is often difficult to assess because hydrologic conditions can change periodically (hourly, daily, or seasonally). Consequently, it is necessary to determine if hydrophytic vegetation and hydric soils are present, which would indicate that water is present for long enough duration to support a wetland plant community. By definition, wetlands are those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands are regulated as "Waters of the United States" by the U.S. Army Corps of Engineers (USACE), as "Waters of the State" by the Washington Department of Ecology (Ecology), and locally by Kitsap County.

Kitsap County and OPG jointly identified the initial route across the park and forestland between Stottlemeyer Road and the Town of Port Gamble. The trail route was walked by ELS biologists to identify the presence of wetlands across or near the proposed trail route from south to north. The wetlands were delineated where they crossed the original route or were in proximity to the trail. As a result of early identification visits, the trail route was realigned to avoid steep slopes and minimize wetland impacts, which necessitated additional site visits to identify wetlands along alternate trail route. The final route is based on the combined decision of Kitsap County and OPG based on recommendations made by the Fischer Bouma team. In general, the final route decision was based on presence of steep slopes along the existing roads that exceed the maximum slope percentages allowed by federal trail standards. The delineated wetland boundaries were located using a hand-held Trimble Global Positioning System unit (GPS) to provide a general location of the wetlands and their boundaries along or adjacent to the trail alignment. The delineation of the

wetland boundaries was determined through breaks in topography, changes in vegetation, and presence of hydrologic indicators. Vegetation, hydrology, and soil data was collected at 29 test plots to verify the wetland boundary mapping and data forms are not included with this report. A general discussion of the data collected in the wetland and upland areas is included. The mapped wetland boundaries are shown on Figures 2 through 4. In addition, ELS biologists identified and mapped culvert crossings along the existing roads in order to determine potential wetland and stream impacts.

# STUDY AREA DESCRIPTION

The trail route examined in this feasibility study is part of a greater effort to connect regions of Kitsap County with non-motorized trails and for the continuation of the Sound to Olympics Trail. The scope of this feasibility encompasses a section about 6 miles long extending between Port Gamble at the north end and Stottlemeyer Road NE at the south end (Figure 2). It passes primarily through the Port Gamble Heritage Park and undeveloped timberland owned by OPG; most of which is woven with interlacing logging roads due to historic and current logging practices. OPG has a past policy of allowing public access to their timberlands that are not being actively logged. As a result, a large system of trails utilized by walkers, bikers, and equestrians will utilize existing logging road and well used paths. Only short segments of the proposed trail will be entirely new. Two potential options were identified by the work group. The Lower Option parallels State Highway 104 and is lower in the watershed than the Upper Option, which primarily follows the ridge. As a result, the Lower Option has greater topographical and critical areas challenges. The Upper Option is west of the Lower Option and occurs along the boundary of several watersheds. The Upper Option represents relatively level topography and fewer critical areas challenges. The length of the proposed trail and the conditions observed during field assessments necessitated dividing the project into three segments defined by regional proximity. The segments are described separately with regard to their position along the trail route, the critical areas observed, and vegetative conditions. In an effort to create trail complexity, two potential connections between the two options were also investigated. Both potential trail options are proposed to begin along State Highway 104 in Port Gamble. The segments are described from north to south beginning at South Teekalet Avenue and ending at the trailhead on the north side of Stottlemeyer Road in Poulsbo (Figures 3 through 5).

### **NORTH SEGMENT**

The north segment begins at the town of Port Gamble and extends south for about a mile and half (Figure 3). This area is composed of undulating terrain from the low north end to the high ridge at the south end. This segment is composed of a relatively level upland forest ridge and logging schedules have left most of the areas vegetated with mature stands of Douglas fir (Photoplates 1 through 3). Wetlands are absent along most of the Upper Option, but there are several well-established beaver pond wetlands at the north end. These wetlands were delineated by consultants for OPG prior to initiation of the feasibility. The boundaries as provided by OPG are provided on the ELS figures. Many culverts convey surface water beneath the logging roads that makes up the Upper Option. The trail follows the ridge's high topography southward into the next segment. The Lower Option passes by many wetland systems as well as stream culverts (Photoplates 1 through 3). Wetlands A through H are all sloping systems located along either side of the Lower Option. A

connecting trail along existing logging roads between the Lower to Upper Option is proposed in this segment to allow a combination of the options to be used and optimization of the final alignment. Several culverts cross the proposed connection, but no wetlands were located.

#### CENTRAL SEGMENT

The central segment begins south of the connecting trail and continues south for about a mile and half. The area is characterized by very level terrain on the Upper Option, and highly variable topography along the Lower Option (Figure 4). Several ravines carve deep into the slope perpendicular to the trail, creating topographical and critical areas challenges. Selective logging and thinning was being conducted in the northern portion of the Lower Option during several of the field visits. Some areas of this segment are very dense with tree cover and are staged for commercial thinning. A second potential connecting trail was investigated in this segment to connect the Upper and Lower Options. The connecting trail would be completely new trail to accommodate the grade requirements, and four wetlands were found in the vicinity of the proposed trail. Wetlands M, N, O and P are depressional forested wetlands and their buffers would potentially have been impacted by the new trail (Photoplate 4), so the potential connection was abandoned in favor of the existing trail in the North Segment. Wetlands K and L are located on either side of the Upper Option just north of forest road 1000, which is oriented west to east (Photoplates 5).

#### **SOUTH SEGMENT**

On the Lower Option, the south segment begins on a trail a couple hundred feet south of the Service Roads 1000 and 1200 intersection (Figure 5). This section of trail is generally at a grade steeper than 5%, and is crossed by several streams (Photoplate 6). Wetlands I and J are located adjacent to the trail in this segment. The Lower Option continues south on both existing roads and trails to Stottlemeyer Road. The south segment of the Upper Option starts on Service Road 1800 a couple hundred feet south of Service Roads 1700 and 1800 intersection. The Upper Option continues south on Service Road 1800 until the road turns east. In the southern end of the Upper Option's South Segment, there are numerous existing trails that extend south from Service Road 1800 that could provide access to the Stottlemeyer Road NE Trailhead. No wetlands were found on the south segment of the Upper Option, and one stream was mapped in the area (Photoplates 7 and 8)

#### VEGETATION

The areas of wetland identified along the trail alignment consisted of forested vegetation communities. The most common plant species in the wetlands include: red alder (*Alnus rubra*, FAC), salmonberry (*Rubus spectabilis*, FAC), youth-on-age (*Tolmeia menziesii*, FAC), lady fern (*Athyrium cyclosorum*, FAC), water parsley (*Oenanthe sarmentosa*, OBL), stinging nettle (*Urtica diocia*, FAC), red canarygrass (*Phalaris arundinacea*, FACW), slough sedge (*Carex obnupta*, OBL), soft rush (*Juncus effusus*, FACW), and creeping buttercup (*Ranunculus repens*, FAC).

The majority of the study area is maintained as timberland planted with Douglas fir (*Pseudotsuga menziesii*, FACU) and western red cedar (*Thuja plicata*, FAC), additional plant species include: red alder, salmonberry, red elderberry (*Sambucus racemosa*, FACU), snowberry (*Symphoricarpos* 

albus, FACU), English holly (*Ilex aquilinum*, FACU), salal (*Gaultheria shallon*, FACU), trailing blackberry (*Rubus ursinus*, FACU), sword fern, and youth-on-age, common horsetail (*Equisetum arvense*, FAC), velvet grass (*Holcus lanatus*, FAC), lady fern, reed canarygrass, and hedge nettle (*Stachys chamissonis spp. cooleyae*, FAC).

The dominant vegetation found onsite is recorded on the attached wetland determination data forms (Appendix A). The indicator status, following the common and scientific names, indicates how likely a species is to be found in wetlands. Listed from most likely to least likely to be found in wetlands, the indicator status categories are:

- **OBL** (obligate wetland) Almost always occur in wetlands.
- **FACW** (facultative wetland) Usually occur in wetlands, but may occur in non-wetlands.
- **FAC** (facultative) Occur in wetlands and non-wetlands.
- **FACU** (facultative upland) Usually occur in non-wetlands, but may occur in wetlands.
- **UPL** (obligate upland) Almost never occur in wetlands.
- NI (no indicator) Status not yet determined.

### Soils

As referenced on the U.S.D.A. Natural Resources Conservation Service (NRCS 2015) website, the following soil types are mapped (Table 1) along the preferred trail alignment (Figure 6). Of the mapped soil units, McKenna soils is the only soil that is classified as hydric and the other soil types mapped along the trail are not classified as hydric, although many have hydric inclusions (NRCS 2017. Areas mapped as hydric soil do not necessarily mean that an area is or is not a wetland—hydrology, hydrophytic vegetation, and hydric soils must all be present to classify an area as a wetland. Table 1 provides the list of soil types found within each segment along the preferred alignment of the trail and identifies whether they are considered hydric soil types.

Table 1: Soil Map Units

| Soil Map Units                                        | Hydric?    |
|-------------------------------------------------------|------------|
| 22 Kapowsin gravelly ashy loam, 0 to 6% slopes        | No         |
| 23 Kapowsin gravelly ashy loam, 6 to 15% slopes       | No         |
| 32 McKenna gravelly loam                              | Yes        |
| 39 Poulsbo gravelly sandy loam, 0 to 6% slopes        | Inclusions |
| 40 Poulsbo gravelly sandy loam, 6 to 15% slopes       | Inclusions |
| 41 Poulsbo gravelly sandy loam, 15 to 30% slopes      | No         |
| 42 Poulsbo-Ragnar complex, 0 to 6% slopes             | Inclusions |
| 43 Poulsbo-Ragnar complex, 6 to 15% slopes            | Inclusions |
| 44 Ragnar fine sandy loam, 0 to 6% slopes             | No         |
| 45 Ragnar fine sandy loam, 6 to 15% slopes            | No         |
| 46 Ragnar fine sandy loam, 15 to 30 % slopes          | No         |
| 59 Sinclair very gravelly sandy loam, 2 to 8% slopes  | Inclusions |
| 60 Sinclair very gravelly sandy loam, 8 to 15% slopes | Inclusions |

The field visits revealed that the soil map units do not accurately reflect wetland and upland conditions along the preferred trail alignment. Hydric mineral soils (low matrix chromas with redoximorphic features) were identified in the wetlands in areas where hydric soils were not mapped. Wetlands A and C through P were identified and delineated in non-hydric soil map units and Wetland B was identified within the McKenna map unit. The soil test holes conducted in these wetlands revealed low matrix chroma, mineral soil conditions. These soil map units are well drained and do not have hydric soil inclusions, however, they either have depressions or form shallow sloping troughs where wetlands can develop as a result of groundwater discharging from the sloping terrain. Upland test plots revealed high soil matrix colors with no indicators of hydric soils present.

## **HYDROLOGY**

Hydrology was present in the delineated wetland areas during each of the late winter and early-spring field visits. A high water table was observed in many of the wetland test holes. Saturated soil conditions were also observed across many of the segments. Permanently flooded, seasonally flooded, or saturated only areas and seasonally flowing streams were observed in wetland areas identified in the trail segments. The sources of hydrology include seepage from slopes (Wetlands A-J), seasonally perched water tables (Wetlands B, K-P), surface water runoff (all wetlands), and stream flooding (areas of Wetland B). Direct precipitation also contributes water to all the wetlands.

# NATIONAL WETLAND INVENTORY

The National Wetlands Inventory (NWI) maps the presence of two palustrine, scrub shrub seasonally flooded wetlands (PSSC) in the North segment, in the vicinity of the preferred alignment (Figure 7). Wetland B was located in this area and was found to be larger than the mapped wetland and is primarily forested. No wetlands were mapped on or within 300 feet of the preferred alignment in the Central and South Segments. The ELS delineation does not agree with the NWI mapping because additional wetlands were identified and delineated in all three segments (Figure 2). The NWI maps should be used with discretion because they are used to gather general wetland information about a regional area and therefore are limited in accuracy for smaller areas because of their large scale.

## KITSAP COUNTY CRITICAL AREAS

The Kitsap County Critical Areas map (KC 2017) identifies wetland in the same orientation as the NWI and identifies potential wetlands in the same orientation as the NRCS (Figure 8). The ELS delineation revealed wetlands along each of the trail segments that are not mapped.

#### CONCLUSIONS

### WETLAND CATEGORIZATION

The wetlands identified and delineated along the trail alignment were categorized according to Washington State Wetlands Rating System for Western Washington,-2014 Update (Rating System)

(Hruby 2014). The wetlands were rated using separate rating forms to determine the appropriate category (Appendix B) and the ratings are summarized in Table 2.

Table 2: Wetland Ratings

| Wetland      | HGM Class    | Vegetation<br>Class     | 2014 Wetland Rating System |            |         |       | Wetland<br>Category |
|--------------|--------------|-------------------------|----------------------------|------------|---------|-------|---------------------|
|              |              | 2 3300                  | Water<br>Quality           | Hydrologic | Habitat | Total | <b>6J</b>           |

### **CRITICAL AREA REGULATIONS**

The *KCC Chapter 19.200* specifies buffers based on wetland category, scores for habitat functions on the rating form, and the intensity of the proposed land uses in accordance with the 2014 wetland rating system. High intensity land use buffer are assigned to this project because the trail will be paved and will have high use by local residents. Required buffers are summarized in Table 3.

Table 3: Wetland Buffers

| Wetlands | Category | <b>Habitat Value Score</b> | <b>Buffer Width (feet)</b> |
|----------|----------|----------------------------|----------------------------|
| В        | III      | 5/6 (moderate)             | 150                        |
| A,C-J    | IV       | 5/6 (moderate)             | 50                         |
| K-P      | IV       | 4 (low)                    | 25                         |

The KCC Chapter 19.300 specifies buffers for streams based on the Washington Department of Natural Resources (DNR) Water Typing System. The stream flowing through culvert number 27 in the South Segment of the study area is not mapped or typed by the DNR's Forest Practices Map, but meets the criteria of a fish-bearing (Type F) stream; the stream has an average bank full width of greater than 36 inches and grade less than 16% (Photoplates 7 and 8). Type F streams require a buffer of 150 feet and building or impervious surface setback of 15 feet.

## FEASIBILITY DISCUSSION

#### PREFERRED ALIGNMENT AND CONSTRUCTION METHODS

The preferred trail alignment begins at State Highway 104 in Port Gamble, and runs south along the Lower Option. The alignment then follows the northern connecting trail to transition to the Upper Option, and then continues south on the Upper Option until Service Road 1800 turns east. Here, to accommodate grade requirements, the alignment leaves the existing road and trail system and cuts southeast, crossing several existing trails before continuing east and ending at Stottlemeyer Road (Figure 5). The trail will be 10 to 14 feet wide and use the existing road base where possible. The active trail area will be constructed of asphalt paving to accommodate pedestrians and bicyclists.

The final trail alignment and widths were determined during the early phases of the feasibility process based on the federal requirements for multi-use trails and the physical constraints identified along the alignment. The physical constraints include steep slopes where the trail width and features required alteration because these sections could not meet the federal slope requirements and identification of wetlands in certain segments of the trail project. Although the preferred alignment has been identified and presented in the feasibility report, the final alignment may vary if significant trees and other vegetation are identified. The trail will only be revised if the new route can avoid or minimize impact to the wetland and significant vegetation.

#### **IMPACT ASSESSMENT**

No wetland fill is proposed for this project. The potential impacts and mitigation measures focus on the construction methods and potential direct wetland, streams, and buffer impacts for which permits are required from the local, state, and federal agencies. No indirect impacts are discussed in this feasibility report but may be included in future mitigation reports and permit documents.

## **Potential Wetland and Buffer Impacts and Mitigation Measures**

In general, there will be no direct impacts to wetlands because the preferred alignment lies along existing roads used for maintenance and logging operations by OPG. The configuration results in

minimal impacts to the identified wetland areas but in some areas will result in temporary vegetation impacts in buffers to accommodate construction in the 10 to 14 foot wide work areas.

Buffer impacts will result from construction of the paved surfaces and removal of vegetation where they extend beyond the existing roadways. However, in some instances, the route is composed of existing roads that lay within the buffers so represents an existing interruption of the buffer and mitigation will not be required unless the construction activities result in additional buffer impacts.

The paved surfaces will also introduce runoff issues into the wetland buffer areas, which could alter the route of water in some areas and result in less discharge of groundwater in others. One area of concern is in the Central Segment of the Upper Option, between Wetlands K and L, where water currently floods over the existing road between the two wetlands. Here, a culvert will need to be placed under the trail to allow the continuation of water flow. Stormwater features constructed along the trail will prevent potential adverse impacts to water quality and quantity on the wetland areas. Permanent vegetation removal will reduce the protection for the wetland areas but once the trail is constructed, areas of the buffer outside the trail area can be enhanced to compensate for the permanent loss of vegetation. The proposed temporary vegetation impact areas will be mitigated once construction is completed. Mitigation measures will include removal of invasive plant species and replanting with native buffer species in the wetland and buffer areas along the trail.

# **Potential Stream and Buffer Impacts and Mitigation Measures**

For most of the alignment there will be no direct impacts to streams or their buffers because the proposed route lies along existing roads used for maintenance and logging operations by OPG. Twenty-seven culverts currently exist along the preferred alignment and new culverts will be installed where needed to allow the continuation of water flow. The culverts observed during the field assessment appear to have been recently replaced and are at least 18 inches in diameter with some culverts 24 inches in diameter where larger flows of water along existing streams are present. Based on these observations, the culverts will likely not require full replacement unless deemed necessary by the local tribes and WDFW.

One new stream crossing is proposed in the South Segment, where the preferred alignment leaves Service Road 1800 and continues southeast (Figure ). Stream and buffer impacts will result from construction of a new crossing and removal of vegetation. An alternative, to avoid and minimize stream impacts, is to reroute the alignment further east to follow Service Road 1800 where there is culvert under the road. This will greatly reduce the impact to the stream and its buffers and reduce permitting and mitigation costs.

The paved surfaces will also introduce runoff issues into the stream buffer areas, which could alter the route of water in some areas and result in less discharge of groundwater in others. Stormwater features constructed along the trail will prevent potential adverse impacts to water quality and quantity on the stream. Permanent vegetation removal will reduce the protection for the stream but once the trail is constructed, areas of the buffer outside the trail area can be enhanced to compensate for the permanent loss of vegetation. The proposed temporary vegetation impact areas will be restored to replace plants once construction is completed. Mitigation measures will include removal of invasive plant species and replanting with native buffer species in the stream and buffer areas along the trail.

## **Mitigation Options and Cost Overview**

This trail project has selected an alignment that basically avoids most impacts to the identified critical areas and buffers because it utilizes the existing road and trail system on the OPG and Port Gamble Heritage Park properties. Since there will be no loss of acreage or function to the wetlands along the preferred alignment, mitigation will focus mostly on compensation for permanent and temporary vegetation removal within both wetland and buffer areas, as needed. The method of compensation for permanent wetland and buffer vegetation impacts will likely be enhancement of wetlands and buffers. In areas where vegetation removal is temporary, the replanting plan will simply restore vegetation in areas that will remain wetland or buffer. Permanent wetland vegetation impacts will be mitigated at the appropriate enhancement ratios for the different wetland categories, which are: Category I - 24:1, Category II - 12:1, Category II - 8:1, and Category IV - 6:1. Permanent buffer impacts are mitigated at a 1:1 ratio. Restoration of wetland and buffer areas where temporary vegetation impacts occur will be at the 1:1 ratio required for buffer impacts. Onsite mitigation is proposed around the existing wetlands where there is invasive plant cover and where disturbance of vegetation has occurred previously.

Enhancement and restoration of vegetation impacts typically has the lowest costs for mitigation because it involves installation of plants in wetland and buffer areas and does not require grading/excavation costs associated with the creation, reestablishment, and rehabilitation mitigation options. The overall cost depends on the number of plants needed to enhance and restore the vegetation areas, which is dependent on the acreage of impact and the mitigation area available for enhancement. Based on the areas of impact and the mitigation ratios, the approximate costs for wetland enhancement will range between \$325,000 and \$350,000 and between \$12,000 and \$15,000 for buffer mitigation. The estimates provided represent the worst case with regard to mitigation ratio, mitigation area required, and the approximate costs for enhancement of wetlands as mitigation, which is based on the cost per plant and installation by professional landscapers. The overall costs for mitigation could change based on final trail alignment, mitigation approach, and plant costs. The costs also assume that enhancement will take place along the trail and in the impacted wetlands once construction is completed.

### REGULATORY AGENCIES WETLAND AND BUFFER PERMITS

The permits needed for construction of the trail through wetlands and buffers vary depending on the level of impact on the wetlands, streams and buffers. Wetland impacts are regulated by the U.S. Army Corps of Engineers (Corps), Washington Department of Ecology (Ecology), and Kitsap County, when proposing filling, ditching, and/or dredging. Hydraulic Project Approvals (HPA) will be required from the Washington Department of Fish and Wildlife for stream crossings that require installation of culverts. Wetland impacts are mitigated to achieve a no net loss of wetland acreage and/or function to compensate for the loss of acreage and function in the impacted wetland. Buffer impacts do not result in direct impacts to wetland areas so are usually regulated only by local agencies.

• **Kitsap County**-Impacts to wetlands and buffers are regulated by Kitsap County and require submittal of Site Development Activity Permit (SDAP). A State Environmental Policy Act (SEPA) checklist must be submitted along with the SDAP permit package. Wetland delineation and wetland/buffer mitigation plan reports are required as part of the SDAP

permit. No individual critical area or wetland permits are required by Kitsap County. Mitigation for wetland impacts are varied and depend on the category of wetland and the method of mitigation (creation/reestablishment, rehabilitation, and/or enhancement). The lowest ratio for mitigation is 1.5:1 for wetland impacts to Category IV wetlands and the highest are 4:1 for Category I wetland impacts when proposing creation/reestablishment. The highest range of ratios is required when enhancement is proposed as compensation for wetland impacts because it does not result in a no-net-loss of wetland acreage. Kitsap County will usually defer to the Corps and Ecology for mitigation of wetland impacts but require submittal mitigation and delineation reports. Buffer impacts are mitigated at a ratio of 1:1.

- U.S. Army Corps of Engineers-The Corps regulates direct impacts to wetland through Section 401 of the Clean Water Act, Nationwide Permit (NWP) process, which requires submittal of wetland delineation and mitigation plan reports along with the Joint Aquatic Resources Permit Application (JARPA). The list of possible NWPs for which a project can apply is extensive and the NWP for a specific project dependent on the type of activity and project proposed. This trail project will likely meet the criteria for NWP 14-Linear Transportation Project or NWP 18-Minor Discharges depending on the extent of impact and whether it meets all of the criteria. As part of the Corps process, cultural resources and biological assessment reports may be required if features of cultural importance are identified in the project area and if there will be impacts to endangered or threatened wildlife species, respectively. The Corps determine if these additional reports will be required. Consultation with the U.S. Fish and Wildlife Service (USFWS) and NOAA Fisheries (NOAA) will be necessary if a biological assessment is required to concur with the results of the assessment.
- Washington Department of Ecology (Ecology)-Ecology regulates direct wetland impacts through the Water Quality Certification (WQC) process. The WQC is issued following issuance of the NWP and is sometimes issued as part of the NWP by the Corps who determines if the project meets the criteria of the WQC. The delineation and mitigation reports submitted to the Corps are also submitted to Ecology during the permitting process.
- Washington Department of Fish and Wildlife (WDFW)-The WDFW issues Hydraulic Project Approval (HPA) for projects proposing to cross or otherwise disturb streams below the Ordinary High Water Mark (OHWM) or critical habitat. An HPA will be required for the culvert crossings of state regulated streams to ensure that the crossings will not have adverse impacts on the stream and habitat areas.

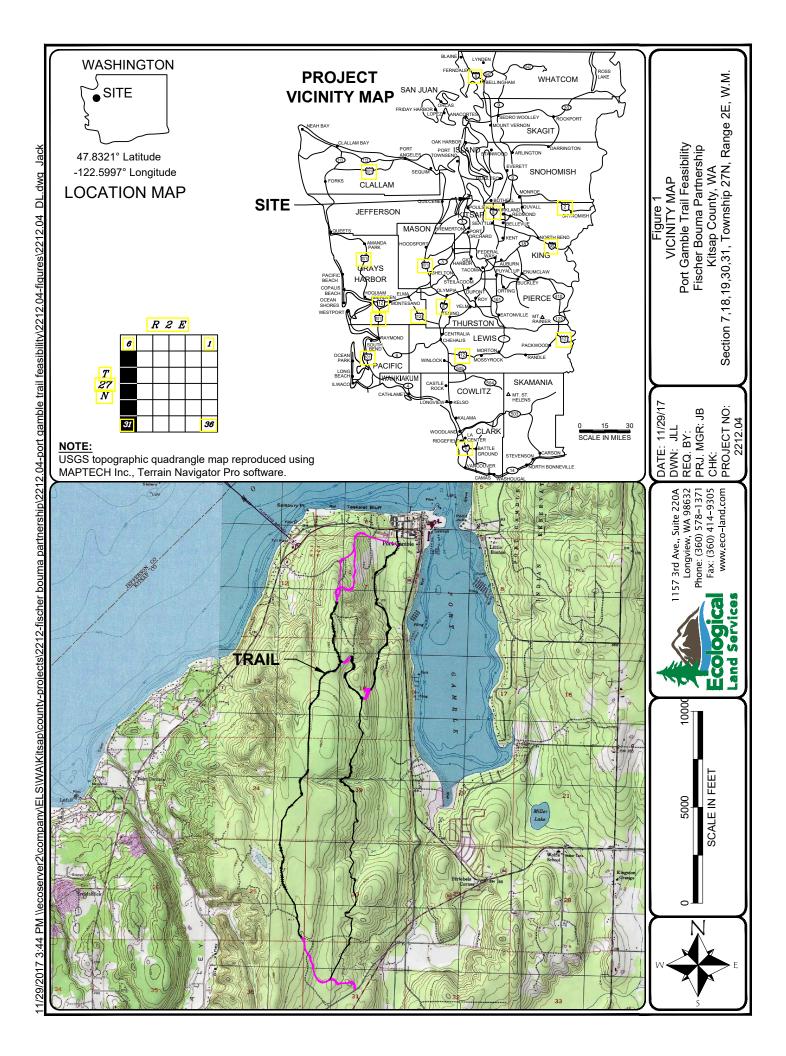

# **LIMITATIONS**

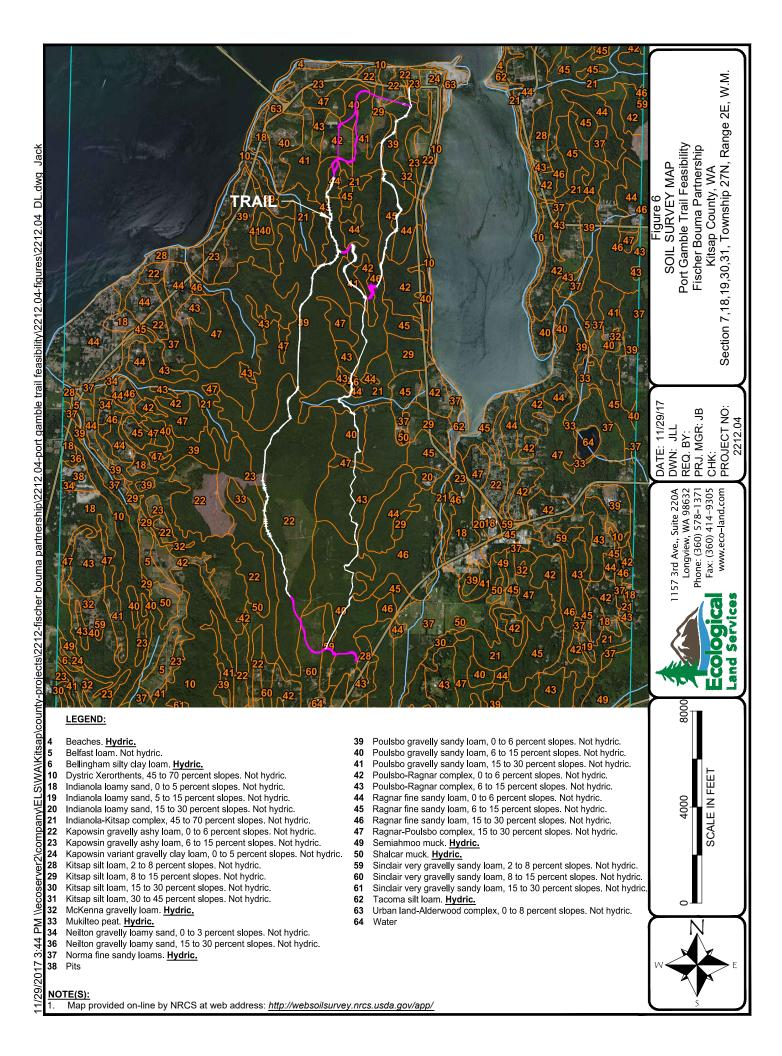

The services described in this report were performed consistent with generally accepted professional consulting principles and practices. There are no other warranties, express or implied. The services preformed were consistent with our agreement with our client. This report is prepared solely for the use of our client and may not be used or relied upon by a third party for any purpose. Any such use or reliance will be at such party's risk.

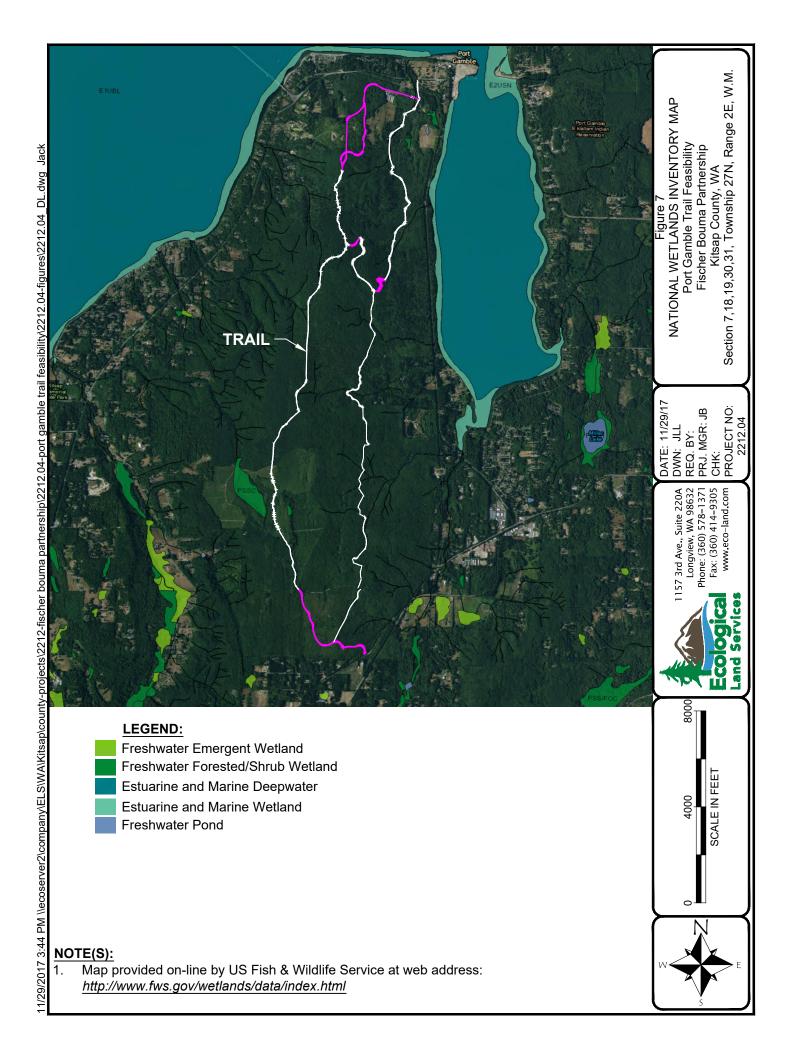

The opinions and recommendations contained in this report apply to conditions existing when services were performed. ELS is not responsible for the impacts of any changes in environmental standards, practices, or regulations after the date of this report. Project Name: Port Gamble Trail Feasibility Client: Fischer Bouma Partnership Kitsap County, Washington

Photo 1 was taken at the north end of the North Segment, at the entrance gate near the start of the Lower Option, looking south. The North Terminus of the Preferred Alignment is just north of here and the trail here will be 10 feet wide and use the existing road base.

**Photo 2** was taken south of the gate in Photo 1 and shows one of the many culverts along the Lower Option. This culvert is where the beaver pond crosses the existing road.

**Photo 3** was taken from the culvert in Photo 2, looking east, into Wetland B. Wetland B is a depressional beaver pond wetland and was forested prior to the impacts of the beaver activity.

| The soil profile most closely matches the description for hydric soil indicateor F3, Depleted Matrix because the depleted matrix begins within 10 inches the soil surface and has distinct mottling.    DROLOGY                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | strictive Layer (if prese                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | nt):                                                       |                   |                     |        | <u> </u>                                                                                                                                                                                                                                    |                                                                                                        |                                                                      | ui.                                           | mode distanced of problematic.                                                                                                                                                                                                                                                                                     |
| The soil profile most closely matches the description for hydric soil indicateor F3, Depleted Matrix because the depleted matrix begins within 10 inches the soil surface and has distinct mottling.    DROLOGY                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | e:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                            |                   |                     |        |                                                                                                                                                                                                                                             |                                                                                                        |                                                                      |                                               |                                                                                                                                                                                                                                                                                                                    |
| The soil profile most closely matches the description for hydric soil indicateor F3, Depleted Matrix because the depleted matrix begins within 10 inches the soil surface and has distinct mottling. SOIL Sampling Point: TP 17 - H Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.) Redox Features Remarks (inches) Color (moist) % Color (moist) % Type<sup>1</sup> Loc<sup>2</sup> Texture 10YR 2/1 100 No redoximorphic features 0-10 sa si lo <u>10-16</u> 10YR 5/1 100 gr sa lo No redoximorphic concentrations sa - sand gr - gravelly si - silt lo - loam <sup>1</sup>Type: C= Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. <sup>2</sup>Location: PL=Pore Lining, M=Matrix, RC=Root Channel Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.) Indicators for Problematic Hydric Soils3: Histosol (A1) Sandy Redox (S5) 2 cm Muck (A10) Histic Epipedon (A2) П Stripped Matrix (S6)  $\Box$ Red Parent Material (TF2) Black Histic (A3) Loamy Mucky Mineral (F1) (except MLRA 1) Very Shallow Dark Surface (TF12) Loamy Gleyed Matrix (F2) Hydrogen Sulfide (A4) Other (Explain in Remarks)  $\boxtimes$ Depleted Below Dark Surface (A11) Depleted Matrix (F3) Thick Dark Surface (A12) Redox Dark Surface (F6) <sup>3</sup>Indicators of hydrophytic vegetation and П Sandy Mucky Mineral (S1) Depleted Dark Surface (F7) wetland hydrology must be present, П Sandy Gleyed Matrix (S4) Redox Depressions (F8) unless disturbed or problematic. Restrictive Layer (if present): Type: **Hydric Soils Present?** Yes  $\boxtimes$ Depth (inches): No Remarks: The soil profile contains a depleted layer with dark chromas above that meet the indicator Depleted Below Dark Surface. The hydric soil criteria is met. **HYDROLOGY** Wetland Hydrology Indicators: Primary Indicators (minimum of one required; check all that apply) Secondary Indicators (2 or more required) П Surface Water (A1) Water-Stained Leaves (B9) Water-Stained Leaves (B9)  $\boxtimes$ High Water Table (A2) (except MLRA 1, 2, 4A, and 4B) (MLRA 1, 2, 4A, and 4B) Saturation (A3) Salt Crust (B11) Drainage Patterns (B10) П Water Marks (B1) Aquatic Invertebrates (B13) П Dry-Season Water Table (C2) Sediment Deposits (B2) Hydrogen Sulfide Odor (C1) Saturation Visible on Aerial Imagery (C9) Geomorphic Position (D2) Drift Deposits (B3) Oxidized Rhizospheres along Living Roots (C3) Algal Mat or Crust (B4) Presence of Reduced Iron (C4) Shallow Aguitard (D3) Iron Deposits (B5) Recent Iron Reduction in Tilled Soils (C6) FAC-Neutral Test (D5) Stunted or Stresses Plants (D1) (LRR A) П Surface Soil Cracks (B6) Raised Ant Mounds (D6) (LRR A) Inundation Visible on Aerial Imagery (B7) Other (Explain in Remarks) Frost-Heave Hummocks (D7) Sparsely Vegetated Concave Surface (B8) Field Observations: Surface Water Present? Yes  $\boxtimes$ No Depth (inches): surface Water Table Present? Yes  $\boxtimes$ No Depth (inches): Saturation Present? Wetland Hydrology Present? Yes  $\boxtimes$ No Yes No  $\boxtimes$ Depth (inches): (includes capillary fringe) Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available: Remarks: Hydrology was present during the field visit observed as saturation at the surface. Therefore the wetland hydrology indicator is met.
